## Economic Default

Why Economic Default Modeling Default  $\tau_r$  and Economic Default  $\tau_e$ Analyzing  $\tau_r$  and  $\tau_e$ Relation to Existing Approaches

Numerical Example

Default Risk and Existing Approaches Recovery Rate Arcsine Law

# Two key quantities in credit risk

- Default processes: the probability of default
- Recovery rate process: the salvage value in case of default

Default Risk and Existing Approaches Recovery Rate Arcsine Law

# Modeling Default

Structural approach: model default via the dynamics of a firm's asset value process S = (S<sub>t</sub>)<sub>t≥0</sub> and debt induced level D,

 $\tau^* = \inf\{t > 0 : S_t \leq D\}.$ 

Merton(1974), Black-Cox (1976), Leland (1994), Leland and Toft (1996)

Reduced-form approach: model the intensity of the arrival of default by an exogenous random process λ<sub>t</sub>.
 <u>Books:</u> Ammann (2001), Bielecki and Rutkowski (2002), Duffie and Singleton (2003), Lando (2004)

Default Risk and Existing Approaches Recovery Rate Arcsine Law

## Two approaches are one

- From a finance view point, the two approaches are related to the information set available to the management or to the market or by adding uncertainty;
- From a probabilistic viewpoint, reduced-form models can be obtained from structural models by conditioning on the smaller information set available to the market or by introducing additional random processes.

Default Risk and Existing Approaches Recovery Rate Arcsine Law

#### **Economic Default**

Why Economic Default Modeling Default  $\tau_r$  and Economic Default  $\tau_e$ Analyzing  $\tau_r$  and  $\tau_e$ Relation to Existing Approaches

Numerical Example

## Arcsine Law

► (P. Lévy) Arcsine Law for the occupation time of Brownian motion W on the positive half line: for 0 ≤ α ≤ t,

$$P_r(\int_0^t \mathbf{1}_{(0,\infty)}(W_s) ds \leq \alpha) = \int_0^{\frac{\alpha}{t}} \frac{ds}{\pi \sqrt{s(1-s)}} = \frac{2}{\pi} \arcsin(\frac{\alpha}{t})^{\frac{1}{2}},$$

• Let  $\theta_t = \sup\{0 \le s \le t : W_s = \max_{0 \le s \le t} W_s\}$ , then

$$P( heta_t \in ds) = rac{ds}{\pi \sqrt{s(1-s)}}$$

• Let  $\gamma_t = \sup\{0 \le s \le t : W_s = 0\}$ , then

$$P(\gamma_t \in ds) = rac{ds}{\pi \sqrt{s(1-s)}}.$$

# Reality check: "data mining" from the market

An empirical study by Guo, Jarrow and Lin (2008) on 2500 defaulted bonds from a datebase with 20 million price quotes over 31000 different issues showed that

- the market anticipates the default before it actually occurs;
- accurate default date is crucial to the recovery rate estimate.

Why Economic Default Modeling Default  $\tau_r$  and Economic Default  $\tau_e$ Analyzing  $\tau_r$  and  $\tau_e$ Relation to Existing Approaches

Numerical Example

Why Economic Default Modeling Default  $\tau_r$  and Economic Default  $\tau_e$ Analyzing  $\tau_r$  and  $\tau_e$ Relation to Existing Approaches

# How to model $\tau_r$ and $\tau_e$ ?

**Key**: what is the economic reason for  $\tau_e$  and  $\tau_r$ ?

# Mathematical models of $\tau_r$ and $\tau_e$

- ► Firm asset value process S = (S<sub>t</sub>, t ≥ 0) is an exponential Lévy process;
- ► The firm needs to pay back its debt at *discrete times* N<sub>1</sub>, N<sub>2</sub>, ..., N<sub>n</sub> where N<sub>k</sub> = kN for some N > 0;
- Real default occurs when the asset value of the firm is less than the threshold D at a time Nk, i.e.

$$\tau_r = \inf\{Nk, S_{Nk} < D\}.$$

Economic default time to be the last time, before the onset of recorded default, where the firm is able to make a debt repayment, i.e.

$$\tau_{\boldsymbol{e}} = \sup_{\tau_r \geq t \geq \tau_r - N} \{t, S_t \geq D\}.$$

Why Economic Default Modeling Default  $\tau_r$  and Economic Default  $\tau_e$ Analyzing  $\tau_r$  and  $\tau_e$ Relation to Existing Approaches

## Default and economic default: illustration

# Outline

#### Some Background

Default Risk and Existing Approaches Recovery Rate Arcsine Law

#### **Economic Default**

Why Economic Default Modeling Default  $\tau_r$  and Economic Default  $\tau_e$ Analyzing  $\tau_r$  and  $\tau_e$ Relation to Existing Approaches

Numerical Example

Why Economic Default Modeling Default  $\tau_r$  and Economic Default  $\tau_e$ Analyzing  $\tau_r$  and  $\tau_e$ Relation to Existing Approaches

# Law of economic default $\tau_e$

$$\tau_{\boldsymbol{e}} = \sup_{\tau_r \geq t \geq \tau_r - N} \{t, S_t \geq D\}.$$

Technical difficulties:

- $\tau_e$  is not a stopping time.
- $\tau_e$  is a last passage time and not a first passage time.
- τ<sub>e</sub> is defined conditioned on the knowledge of the real default τ<sub>r</sub>.

# Simple idea

- Consider  $P_r(\tau_r \tau_e | \tau_r)$
- The unconditioned law of *τ<sub>e</sub>* − *τ<sub>r</sub>* is obtained by summing over all *n* ≥ 1.
- $\rightarrow$  For exponential of spectrally positive Lévy process,  $\tau_r \tau_e$  is a mixture of Arcsine law.

## Example

Let  $S = (S_t, t \ge 0)$  be a geometric Brownian motion so that  $S_t = \exp(\mu W_t - \mu^2 t/2)$  under a risk neutral measure. Then, according to Yor et. al. (2008),

$$\mathbb{P}_{(u,D)}[\tau_r - \tau_e \in ds | \tau_r = N] = \frac{ds}{\pi \sqrt{s(N - u - s)}} \phi(\mu/2\sqrt{N - u - s}).$$

with  $\phi(\mu) = \int_0^\infty dt e^{-t} \cosh(\mu \sqrt{2t})$ .

## Law of default $\tau_r$

$$\tau_r = \inf\{Nk, S_{Nk} < D\}.$$

- $\tau_r$  is the first hitting time of a random walk  $X = \{X_n = \log S_{nN}\}$  hitting level log *D*;
- Analytical expression for \(\tau\_r\) using classical theory of random walk when debt level is constant or linear.

Why Economic Default Modeling Default  $\tau_r$  and Economic Default  $\tau_e$ **Analyzing**  $\tau_r$  and  $\tau_e$ Relation to Existing Approaches

# Analytical expression for $\tau_r$

Given a random walk {log  $S_{Nn}$ } with an i.i.d sequence of { $Y_n$ } with a common distribution F and its associated green function  $U^+$  and  $U^-$ . For any  $y > 0, k \ge 1$ ,

$$P_{r}[\tau_{r} = kN, \log S_{\tau_{r}} \in dy] = \int_{0}^{\infty} \int_{0}^{y} \sum_{i=0}^{k-1} U^{-}(x - pN + y, k - i)U^{+}(dv - y, i)F(v - du).$$

 Some Background
 Why Economic Default

 Economic Default
 Modeling Default τ<sub>r</sub> and Economic Default τ<sub>e</sub>

 Numerical Example
 Analyzing τ<sub>r</sub> and τ<sub>e</sub>

 Concluding Remarks
 Relation to Existing Approaches

# Green function and computation

Green functions of a random walk X is defined by its ladder time T = {T<sub>n</sub> = (T<sup>+</sup><sub>n</sub>, T<sup>−</sup><sub>n</sub>)} and ladder height process H = {H<sub>n</sub> = (H<sup>+</sup><sub>n</sub>, H<sup>+</sup><sub>n</sub>)}

$$U^+(dx,i) = \sum_{\substack{n=0\\\infty}}^{\infty} P_r(H_i^+ \in dx, \ T_i^+ = n),$$

$$U^{-}(dx,i) = \sum_{n=0}^{\infty} P_{r}(H_{i}^{-} \in dx, T_{i}^{-} = n).$$

 From a computational perspective, Green functions can be derived by inverting appropriate Laplace transforms, such as from the well-known Friedst formula

$$1 - \mathbb{E}[r^{T_1^+}e^{itH_1^+}] = \exp(-\sum_{n=1}^{\infty}\frac{r^n}{n}\mathbb{E}[e^{it\log(S_{Nn})}:S_{nN}>1]).$$

Why Economic Default Modeling Default  $\tau_r$  and Economic Default  $\tau_e$ Analyzing  $\tau_r$  and  $\tau_e$ Relation to Existing Approaches

Default Risk and Existing Approaches Recovery Rate Arcsine Law

#### **Economic Default**

Why Economic Default Modeling Default  $\tau_r$  and Economic Default  $\tau_e$ Analyzing  $\tau_r$  and  $\tau_e$ Relation to Existing Approaches

Numerical Example

## Relation to existing approaches

Simple application of Invariance Principle via appropriate scaling shows

- ► The classical structural model is a limiting case of our model as N → 0.
- For better understanding of default, both discrete time and continuous time spaces are needed.
- Firm value process's parameter (either BM based or a more general Lévy model) can be estimated using the tail index and correlation structure of the firm's return.
   For example, the volatility coefficient of the firm value process σ<sub>f</sub> is

$$\sigma_f^2 = \frac{\mathbb{E}[Y_1^2] + 2\sum_{k=2}^{\infty} Cov(Y_1, Y_k)}{N}.$$

## Example

The dynamics of the firm is a geometric Brownian motion,  $\sigma = 0.25, r = 0.04$ . Leverage = 0.8, T = 3 months,  $B_1 = ... = B_8 = 0.4$ .

## Example

The dynamics of the firm is a geometric Brownian motion,  $\sigma = 0.25, r = 0.04$ . Leverage = 0.8, T = 3 months,  $B_1 = ... = B_8 = 0.4$ .

# Summary

- New concept and model of "economic default" is proposed and analyzed
- Quantitative analysis of default and economic default is consistent with empirical observation
- Many interesting problems follow, e.g.
  - pricing and hedging of credit derivatives under the new paradigm
  - probability questions involving Lévy processes, random walk, last passage time.
